Profiling post-COVID-19 condition across different variants of SARS-CoV-2: a prospective longitudinal study in unvaccinated wild-type, unvaccinated alpha-variant, and vaccinated delta-variant populations

Liane S Canas, Erika Molteni, Jie Deng, Carole H Sudre, Benjamin Murray, Eric Kerfoot, Michela Antonelli, Khaled Rjoob, Joan Capdevila Pujol, Lorenzo Polidori, Anna May, Marc F Österdahl, Ronan Whiston, Nathan J Cheetham, Vicky Bowyer, Tim D Spector, Alexander Hammers, Emma L Duncan, Sebastien Ourselin, Claire J Steves, Marc Modat

Summary

Background Self-reported symptom studies rapidly increased understanding of SARS-CoV-2 during the COVID-19 pandemic and enabled monitoring of long-term effects of COVID-19 outside hospital settings. Post-COVID-19 condition presents as heterogeneous profiles, which need characterisation to enable personalised patient care. We aimed to describe post-COVID-19 condition profiles by viral variant and vaccination status.

Studio Cormor

- Studio prospettico dei pazienti positivi della prima ondata (marzo-Maggio 2020) diagnosticati ad Udine
- Tutti i pazienti da asintomatici ad intubati

We performed a bidirectional cohort study design in a tertiary care teaching hospital (Udine, Italy, 1000 beds) designated as a regional centre for COVID-19 patients and serving approximately 350 000 citizens. The reference Ethics Committee (CEUR-2020-OS-219 and CEUR-2020-OS-205) approved the study and all procedures were in accordance with the ethical standards of the Health Care Trust.

A cohort of all consecutive adult in- and out-patients ($\geq$18 years) attending the Infectious Disease Department with a diagnosis of COVID-19 from 1 March to 30 May 2020 were eligible. Patients who were willing to participate were included and a database concerning their demographic, clinical and laboratory data was populated. Six

Studio Cormor

- Circa 1000 pazienti con Covid-19 nella prima ondata ad Udine
- 599 pazienti sono stati arruolati, 241 con sintomi long covid e 358 no
- Sierologia che identificava solo anticorpi anti-spike prodotti durante l’infezione

Low risk of reinfections and relation with serological response after recovery from the first wave of COVID-19

Maddalena Peghin[1] · Emilio Bouza[2,3,4,5] · Martina Fabris[6,7] · Maria De Martino[8] · Alvisa Palese[9] · Giulia Bontempo[1] · Elena Graziano[1] · Valentina Gerussi[1] · Valentina Bressan[9] · Assunta Sartor[6] · Miriam Isola[8] · Carlo Tascini[1] · Francesco Curcio[6]

(2/137, 1.5%), or seropositive (2/353, 0.6%) ($p = 0.085$). All reinfections were mild ($n = 5$) or asymptomatic ($n = 1$). After reinfection, none of patients developed IgM response and only two had a transitory boosted IgG immunization response. In an unselected population after the first wave of COVID-19, after a prolonged observation period (mean 10 months), reinfection was very uncommon; occurred in patients with a previous history of mild infection, mostly with weak or absent serological response; and manifested with mild or asymptomatic clinical presentation.

Post–COVID-19 syndrome and humoral response association after 1 year in vaccinated and unvaccinated patients

Maddalena Peghin [1,2,*], Maria De Martino [3], Alvisa Palese [4], Valentina Gerussi [1], Giulia Bontempo [1], Elena Graziano [1,2], Erica Visintini [4], Denise D'Elia [1], Fabiana Dellai [1], Francesco Marrella [1], Martina Fabris [5], Francesco Curcio [5], Assunta Sartor [5], Miriam Isola [3], Carlo Tascini [1]

479 pazienti furono intervistati 13 mesi dopo infezione acute, long COVID 47%
Misura di anticorpi anti RBD e non-RDB.
Titolo degli Ab non-RDB era correlato al long covid
Titolo degli Ab RDB non correlava con long-Covid, pertanto la vaccinazione non correlava con long-COVID

Results: A total of 479 patients (52.6% female; mean age: 53 years) were interviewed 13.5 months (standard deviation: 0.6 months) after acute infection. Post–COVID-19 syndrome was observed in 47.2% of patients ($n = 226$) after 1 year. There were no significant differences in the worsening of post–COVID-19 symptoms (22.7% vs. 15.8%; $p = 0.209$) among vaccinated ($n = 132$) and unvaccinated ($n = 347$) patients. The presence of non-RBD SARS-CoV-2 IgG induced by natural infection showed a significant association with post–COVID-19 syndrome (OR: 1.35; 95% CI, 1.11–1.64; $p = 0.003$), and median non-RBD SARS-CoV-2 IgG titres were significantly higher in long haulers than in patients without symptoms (22 kAU/L (interquartile range, 9.7–37.2 kAU/L) vs. 14.1 kAU/L (interquartile range, 5.4–31.3 kAU/L); $p = 0.009$) after 1 year. In contrast, the presence of RBD SARS-CoV-2 IgG was not associated with the occurrence of post–COVID-19 syndrome (>2500 U/mL vs. 0.9–2500 U/mL; OR: 1.36; 95% CI, 0.62–3.00; $p = 0.441$), and RBD SARS-CoV-2 IgG titres were similar in long haulers as in patients without symptoms (50% values > 2500 U/mL vs. 55.6% values > 2500 U/mL; $p = 0.451$).

COVID-19 Survivors Are Still in Need of Neuropsychiatric Support Two Years after Infection

Marco Colizzi [1,2,*], Maddalena Peghin [3,4], Maria De Martino [5], Giulia Bontempo [3], Stefania Chiappinotto [6], Federico Fonda [6], Miriam Isola [5], Carlo Tascini [3], Matteo Balestrieri [1] and Alvisa Palese [6]

La gravità della dispnea ed in numero dei sintomi correlavano con i **sintomi psichiatrici a 24 mesi**, specie la perdita di concentrazione

Table 4. Lack of concentration and focus at the 24-month follow-up.

Risk Factors at Onset	Multivariable Analysis		
	OR	95% CI	*p*-Value
Co-morbidities, number	1.52	1.12, 2.08	0.008
Overall symptoms, number	1.09	0.87, 1.38	0.456
Fatigue	1.43	0.62, 3.27	0.398
Dyspnoea	3.17	1.40, 7.16	0.005
Management			
Outpatient	1		
Ward	0.74	0.33, 1.68	0.469
Intensive care unit	1.21	0.31, 4.77	0.783

URTI, upper respiratory tract infection.

Dyspnea at the onset predicted both symptoms of psychiatric disorders (OR = 3.26, 95% CI = 1.22–8.70, and $p = 0.019$) and a lack of concentration and focus (OR = 3.17, 95% CI = 1.40–7.16, and $p = 0.005$) 24 months post-infection, with the number of comorbidities at the onset also predicting the occurrence of a lack of concentration and focus (OR = 1.52, 95% CI = 1.12–2.08, and $p = 0.008$). The findings of this study may have important public health implications, as they underlie the fact that COVID-19 survivors are still in need of neuropsychiatric support two years after infection.

Post-COVID-19 Syndrome 2 Years After the First Wave: The Role of Humoral Response, Vaccination and Reinfection

Maddalena Peghin,[1,a,©] Maria De Martino,[2,a] Alvisa Palese,[3] Stefania Chiappinotto,[3] Federico Fonda,[3] Valentina Gerussi,[4] Assunta Sartor,[5,6] Francesco Curcio,[5] Paolo Antonio Grossi,[1] Miriam Isola,[2,a] and Carlo Tascini[4,a]

[1]Infectious and Tropical Diseases Unit, Department of Medicine and Surgery, University of Insubria-ASST-Sette Laghi, Varese, Italy, [2]Division of Medical Statistic, Department of Medicine, University of Udine, Udine, Italy, [3]Department of Medicine, University of Udine, Udine, Italy, [4]Infectious Diseases Division, Department of Medicine, University of Udine and Azienda Sanitaria Universitaria Friuli Centrale (ASUFC), 33100 Udine, Italy, [5]Institute of Clinical Pathology, Department of Laboratory Medicine, University of Udine, ASUFC,Udine, Italy, and [6]Department of Medicine (DAME), University of Udine, Udine, Italy

Background. The aim of this study was to describe the long-term evolution of post-COVID-19 syndrome over 2 years after the onset of severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) in survivors of the first wave.

Methods. This prospective study was based on interviews and investigated post-COVID-19 syndrome 6, 12, and 24 months after the disease onset in all adult in- and outpatients with COVID-19 followed at Udine Hospital (Italy) during the first wave (March–May 2020). Humoral response, vaccination status, and reinfection were assessed.

Results. Overall, 230 patients (53.5% female; mean age 54.7 years) were interviewed 2.3 years (standard deviation = 0.11) after acute onset. Post-COVID-19 syndrome was observed in 36.1% of patients (n = 83) at 2 years. The most common persistent symptoms were fatigue (14.4%), rheumatological (14.4%), and psychiatric symptoms (9.6%). Overall, 55.4% (46 of 83) of long haulers searched for healthcare system support and 21 (45.7%) were visited by a specialist. Female gender (odds ratio [OR] = 2.50, $P = .005$), a proportional increase in the number of symptoms during acute COVID-19 (OR = 1.40, $P = .001$), and the presence of comorbidities (OR = 1.57, $P = .004$) were all independent risk factors for post-COVID-19 syndrome. Vaccination and reinfection had no impact on post-COVID-19 syndrome dynamics. The presence of receptor-binding domain (RBD) SARS-CoV-2 immunoglobulin G (IgG) and non-RBD SARS-CoV-2 IgG titers were not associated with the occurrence of post-COVID-19 syndrome.

Conclusions. Two years after COVID-19, the burden of persistent symptoms remains high among in- and outpatients' population infected during the first wave. Post-COVID-19 dynamic does not seem to be influenced by SARS-CoV-2 immunization status and reinfection.

Abstract: Although Omicron appears to cause less severe acute illness than the original strain, the potential for large numbers of patients to experience long COVID is a major concern. Little is known about the recovery phase in cases of Omicron, highlighting the importance of dynamically monitor long COVID in those patients. Subjects of the current study were patients available for a three-month follow-up who were admitted from January 13 to May 22, 2020 (period of the original strain) and from January 1 to May 30, 2022 (period of Omicron). Twenty-eight-point-four percent of patients infected with the original strain had long-term symptoms of COVID-19 and 5.63% of those infected with the

Profiling post-COVID-19 condition across different variants of SARS-CoV-2: a prospective longitudinal study in unvaccinated wild-type, unvaccinated alpha-variant, and vaccinated delta-variant populations

Liane S Canas, Erika Molteni, Jie Deng, Carole H Sudre, Benjamin Murray, Eric Kerfoot, Michela Antonelli, Khaled Rjoob, Joan Capdevila Pujol, Lorenzo Polidori, Anna May, Marc F Österdahl, Ronan Whiston, Nathan J Cheetham, Vicky Bowyer, Tim D Spector, Alexander Hammers, Emma L Duncan, Sebastien Ourselin, Claire J Steves, Marc Modat

Summary

Background Self-reported symptom studies rapidly increased understanding of SARS-CoV-2 during the COVID-19 pandemic and enabled monitoring of long-term effects of COVID-19 outside hospital settings. Post-COVID-19 condition presents as heterogeneous profiles, which need characterisation to enable personalised patient care. We aimed to describe post-COVID-19 condition profiles by viral variant and vaccination status.

Procedures

In this study, we used CSS data reported between March 24, 2020, and Dec 8, 2021, and CSS Biobank data gathered between October, 2020, and April, 2021. We defined people with post-COVID-19 condition as those reporting symptoms for longer than 12 weeks after their first positive PCR or lateral flow test within the study period, as per the UK National Institute for Health and
